Conditional cooperation with longer memory

Introduction

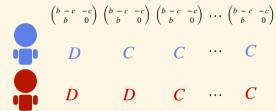

Human cooperative behavior is governed by direct reciprocity. This mechanism for cooperation can explain why people return favors, why they show more effort in group tasks when others do, or why they stop cooperating when they feel exploited. The main theoretical framework to describe reciprocity is the **repeated prisoner's dilemma.**

What is the prisoner's dilemma?

A two players game, who repeatedly decide whether to cooperate (C) or to defect (D) with one another.

What is the repeated prisoner's dilemma?

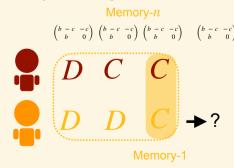

What is a strategy?

a strategy is a plan that dictates a player's actions at each stage based on the entire history of the game/

Current work

Most theoretical research on the evolution of reciprocity focuses on memory-1 strategies.

A formal analysis of strategies with more than one-round memory has been difficult for two reasons:

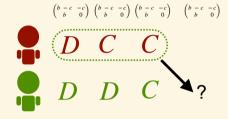

- 1. As the memory length n increases, strategies become harder to interpret.
- 2. The number of strategies, and the time it takes to compute their payoffs, increases dramatically in n.

Can we say anything about reNash in the repeated prisoner's dilemma?

Our approach

We focus on an easy-to-interpret subset of memory-n strategies, the **reactive-**n **strategies**. Capturing the basic premise of conditional cooperation, they only depend on the *co-player's* actions during the last n rounds.

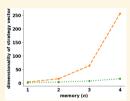

Reactive-n

Definition. A reactive-n strategy can be defined as 2^n -dimensional vector

$$\mathbf{p} = (p_{\mathbf{h}^{-\mathbf{i}}})_{\mathbf{h}^{-\mathbf{i}} \in H^{-i}}$$
 with $0 \le p_{\mathbf{h}^{-\mathbf{i}}} \le 1$

where h^-i its a history from all the possible histories of the co-player..

Nash in higher *n*

We have developed a general algorithm to determine if a given reactive-n strategy is a Nash equilibrium for any n.

To achieve this, we established the following technical result:

- Against reactive strategies, any feasible payoff can be generated with selfreactive strategies.
- To any reactive strategy, there is a best response among the pure self-reactive strategies.

Cooperative Nash

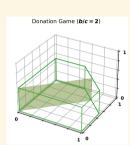

Theorem. A reactive-2 strategy can be defined as the vector

 $\mathbf{p}=(p_{CC},p_{CD},p_{DC},p_{DD})\text{, and it is a cooperative Nash strategy if and only if, the strategy entries satisfy the conditions,}$

$$p_{CC} = 1,$$

$$\frac{p_{CD} + p_{DC}}{2} < 1 - \frac{1}{2} \cdot \frac{c}{b}$$

$$p_{DD} \le 1 - \frac{c}{b}.$$

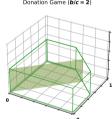

Defective Nash

Theorem. A reactive-2 strategy can be defined as the vector

 $\mathbf{p} = (p_{CC}, p_{CD}, p_{DC}, p_{DD}), \text{ and it is a cooperative Nash strategy if and only if, the strategy entries satisfy the conditions, Donation Game (b/c = 2)$

$$\begin{split} p_{CC} &= 1, \\ \frac{p_{CD} + p_{DC}}{2} &< 1 - \frac{1}{2} \cdot \frac{c}{b} \\ p_{DD} &\leq 1 - \frac{c}{b} \,. \end{split}$$
